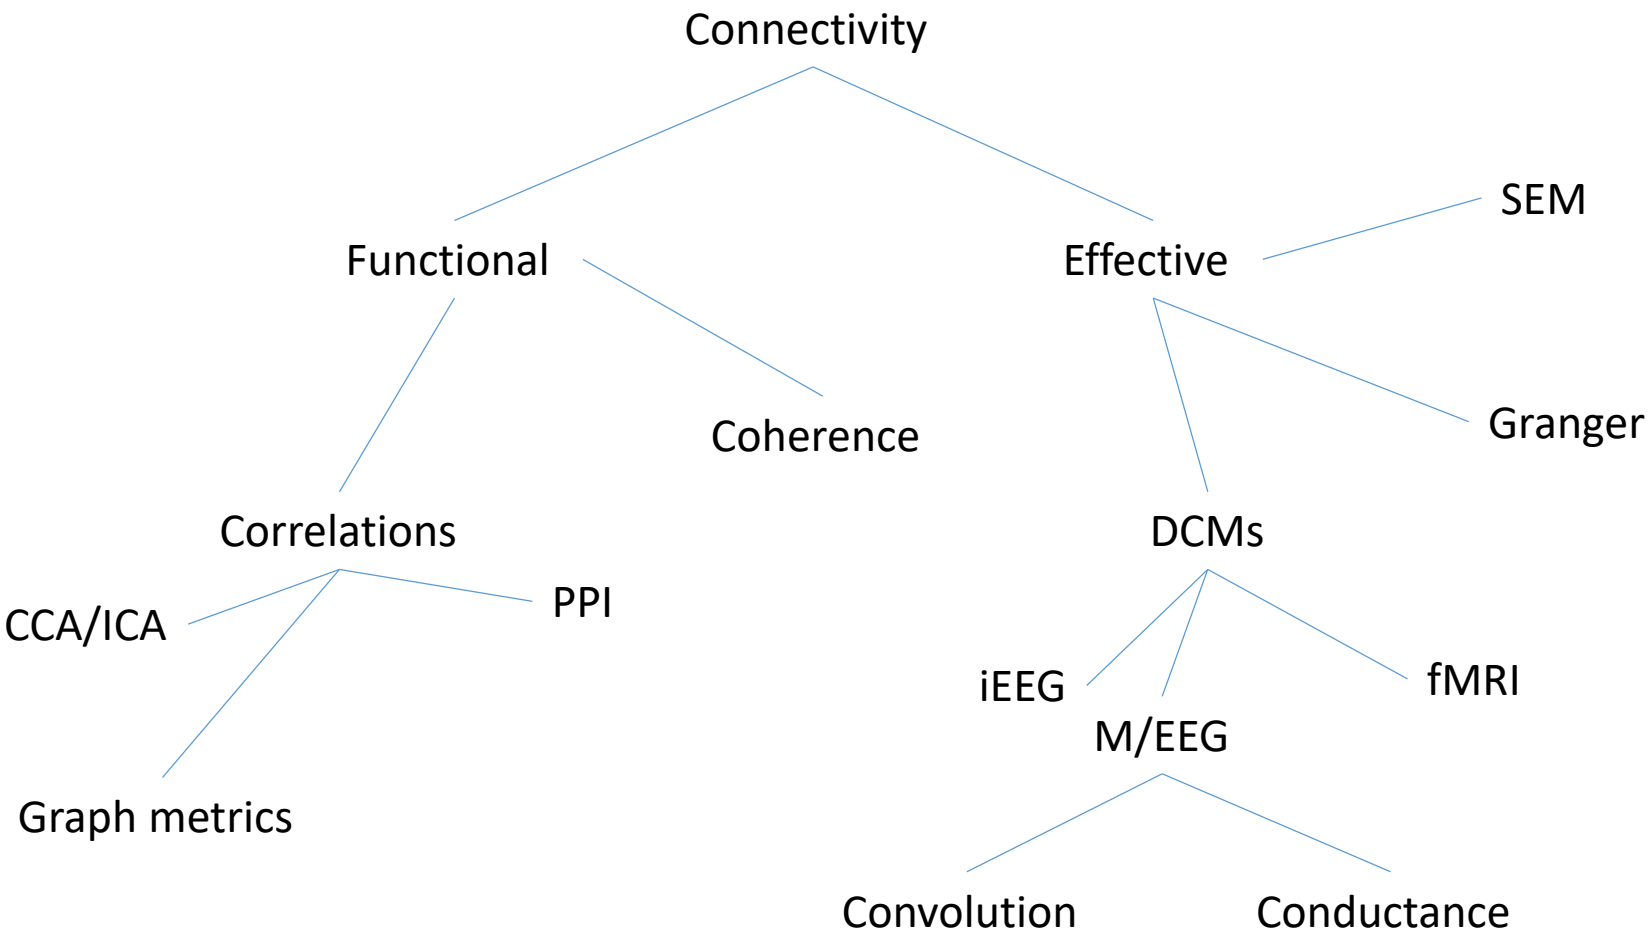
Disclosures

- Research grants from Janssen, Lilly, AstraZeneca
- Consultancies/advisory board for Asceneuron, Astronautx, Biogen, Curasen, SVHealth, ICG, WAVE, Astex, Prevail, UCB
- Chief Scientific Adviser to Alzheimer Research UK
- Chief Investigator CNS101 (CumulusNeuro)

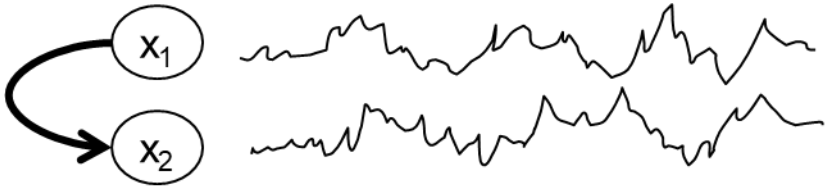
The pharmacology studies described today are unrelated to the above; and represent research only, not clinical advice.

A family of brain connectivity methods



Dynamic Causal models

- Dynamic



$$x(t) = \begin{bmatrix} x_1(t) \\ \vdots \\ x_n(t) \end{bmatrix}$$

overall system state represented by state variables

$$\frac{dx}{dt} = \dot{x} = \begin{bmatrix} \dot{x}_1 \\ \vdots \\ \dot{x}_n \end{bmatrix}$$

change of state vector in time

*System **dynamics*** = change of state vectors in time

Connectivity as time constants

Dynamic Causal models

- Dynamic
- Causal

Causal *effects* in the system:

interactions between elements

events in the world *u*

system parameters θ

$$\dot{x} = F(x, u, \theta)$$

Including connectivity x1 → x2 versus x2 → x1

Dynamic Causal models

- Dynamic
- Causal
- Models

$$\dot{\boldsymbol{z}} = f\left(\boldsymbol{z}, \boldsymbol{U}, \boldsymbol{\theta}^{(n)}\right)$$

$$\boldsymbol{y} = g\left(\boldsymbol{z}, \boldsymbol{\theta}^{(h)}\right) + \boldsymbol{X}_0\boldsymbol{\beta}_0 + \varepsilon$$

$$\begin{aligned} \dot{\boldsymbol{z}} &= \boldsymbol{J}\boldsymbol{z} + \boldsymbol{C}\boldsymbol{u}(t) \\ \boldsymbol{J} &= \left(\boldsymbol{A} + \textstyle\sum_k \boldsymbol{B}^{(k)}\, \boldsymbol{u_k}(t)\right) \end{aligned}$$

$$\boldsymbol{J} = \underbrace{-0.5 \cdot \exp\left(\boldsymbol{A_I}\right) \cdot \exp\left(\sum_k \boldsymbol{B_I^{(k)}}\, \boldsymbol{u_k}(t)\right)}_{Intrinsic\ (self-inhibition)} + \underbrace{\left(\boldsymbol{A_E} + \sum_k \boldsymbol{B_E^{(k)}}\, \boldsymbol{u_k}(t)\right)}_{Extrinsic\ (between-region)}$$

A – baseline connectivity
B – task modulation
C - Driving inputs
U – task events

Dynamic Causal models

- Dynamic
- Causal
- Models

$$\dot{\boldsymbol{z}} = f\left(\boldsymbol{z}, \boldsymbol{U}, \boldsymbol{\theta}^{(n)}\right)$$
$$\boldsymbol{y} = g\left(\boldsymbol{z}, \boldsymbol{\theta}^{(h)}\right) + \boldsymbol{X}_0\boldsymbol{\beta}_0 + \varepsilon$$

hypotheses tested in terms of parameters
hypotheses tested in terms of model comparison

Historical comparison: AIC, BIC, GBF, BRFX, ….
Now free energy F ~ log(model_evidence)
= accuracy – complexity

Estimating the parameters….

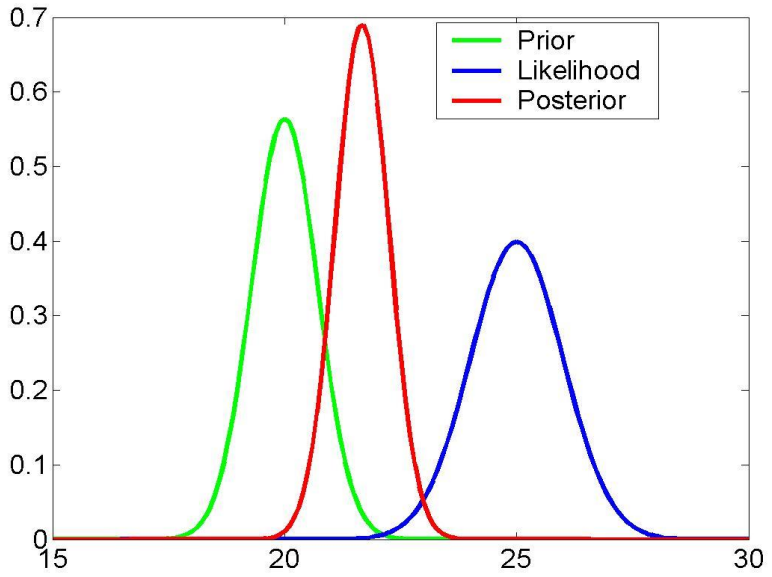
- Priors used to inform Bayesian parameter estimation
- express prior knowledge (belief) about parameters of the model
- Update beliefs according to the new evidence (and precision)
- hemodynamic parameters and connectivity parameters

Bayes Theorem

$$p(\theta \mid y) \propto p(y \mid \theta) \cdot p(\theta)$$

posterior $\propto$ likelihood $\cdot$ prior

updated belief $\propto$ new data $\cdot$ old belief



Bayesian Model Selection

Bayes theorem:

$$p(\theta \mid y, m) = \frac{p(y \mid \theta, m)\, p(\theta \mid m)}{}$$

Model evidence:

$$p(y \mid m) = \int p(y \mid \theta, m) \cdot p(\theta \mid m)\, d\theta$$

Bayes factor B:

compare two models i and j by the ratio of probabilities

$$B_{ij} = \frac{p(y \mid m = i)}{p(y \mid m = j)}$$

$$F \approx \log p(y \mid m) = accuracy(m) - complexity(m)$$

$$\Delta F_{ij} = F_i - F_j$$

Bayesian Model Selection

Bayes theorem:

$$p(\theta \mid y, m) = \frac{p(y \mid \theta, m)\, p(\theta \mid m)}{}$$

Model evidence:

$$p(y \mid m) = \int p(y \mid \theta, m) \cdot p(\theta \mid m)\, d\theta$$

Bayes factor B:

compare two models i and j by the ratio of probabilities

$$B_{ij} = \frac{p(y \mid m = i)}{p(y \mid m = j)}$$

B_{12}	$p(m_1 \mid y)$	Evidence	ΔF
1 to 3	50-75%	weak	
3 to 20	75-95%	positive	>1.1
20 to 150	95-99%	strong	>3
≥ 150	≥ 99%	Very strong	>5

$$\Delta F_{ij} = F_i - F_j$$

Group studies

Historical AIC, BIC, group-Bayes-factor (sum over individuals)… but vulnerable to outliers

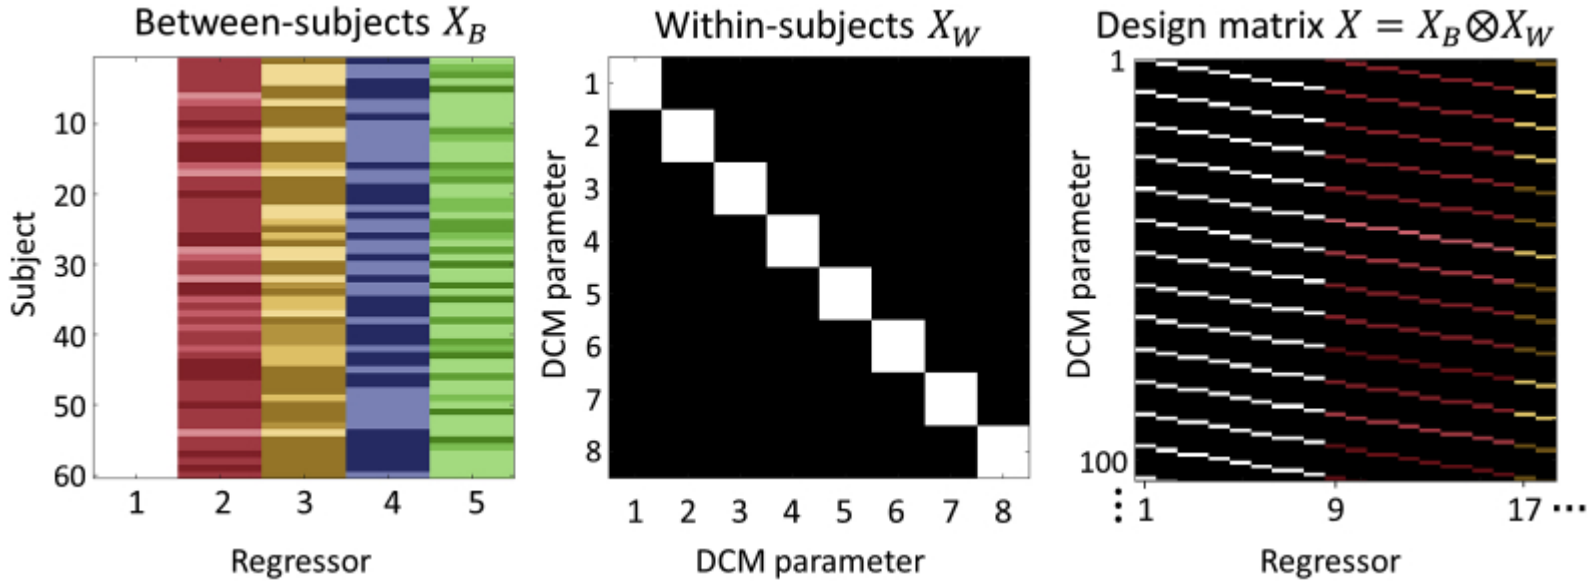
Then “Random Effects” models selection

specify multiple DCMs per subject then estimate the relative probability that any randomly selected person from the population would have had their data generated by each model (ie random effect over models)

Parametric Empirical Bayes (PEB)

Random effects on parameters rather than models. All subjects have the same basic architecture, but differ in terms of connection strength in that model

PEB



If mean-centred, then the first column of ones corresponds to mean experiment-related changes in connectivity over subjects, and between-subject effects add to this.

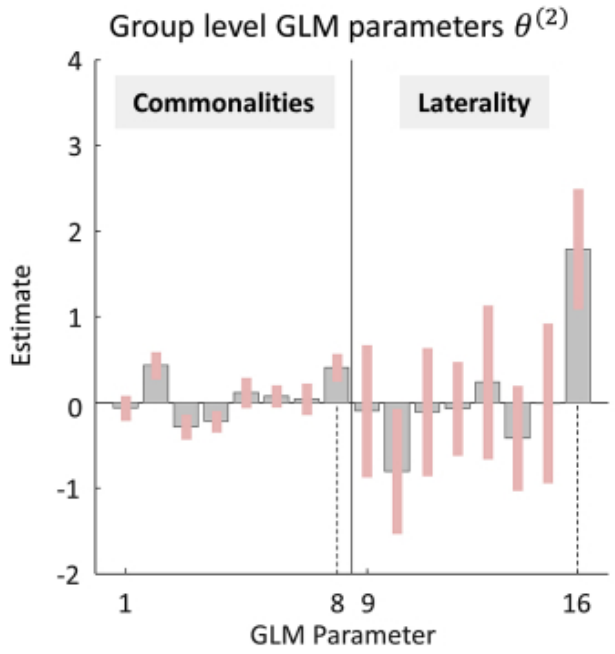
Ie the first regressor represents group mean effective connectivity.

which DCM connectivity parameters can receive between-subject effects

what the experimental (between-subject) effects act on; ie. which (within-subject) parameters

PEB

invert the PEB model (**spm_dcm_peb.m**) to get two useful quantities:
the estimated group-level parameters
and the group-level free energy



$F^2 \sim \text{Log } p(Y|m)$

F ~ log of the probability of observing the neuroimaging data (from all subjects) given the entire hierarchical model m.
Sum of all subjects' DCMs accuracies, minus the complexity induced *and the second-level GLM*.
Can compare free energy of PEB models with different sets of parameters switched on and off to find the optimal explanation for the dataset as a whole.

PEB

invert the PEB model (**spm_dcm_peb.m**) to get two useful quantities:
the estimated group-level parameters
and the group-level free energy

Where multiple factors are subject to multiple covariates the number pf models of very large – so consider to reduce to model "families" (cf standard DCM)

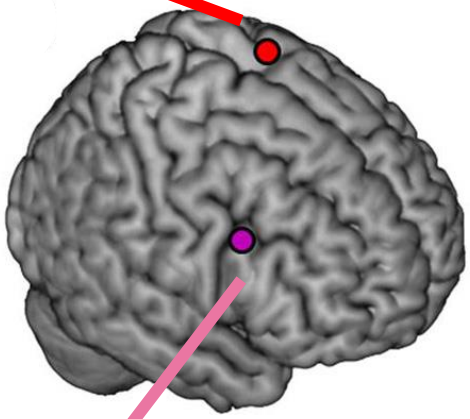
Or Bayesian Model Reduction (BMR): free energy and parameters for 'reduced' models are computed analytically. The difference between a full and reduced models is their priors (eg. some connections switched off, spm_log_evidence_reduce.m)

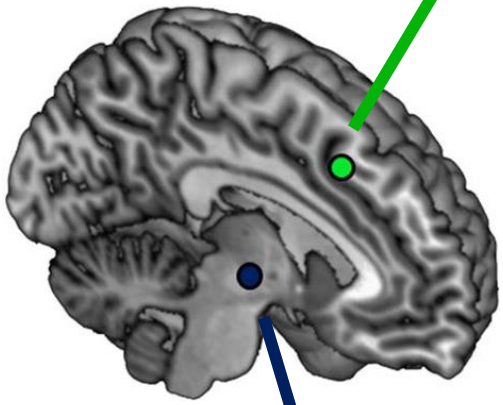
fMRI

How to stop what you are doing?

Motor cortex (M1)
Source of corticospinal projections for motor control

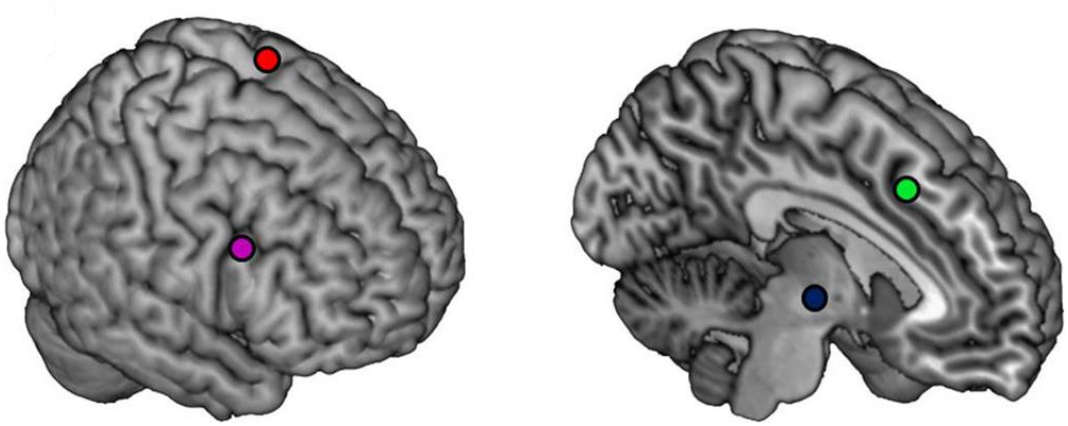
preSMA
(i) Selection of action
(ii) For inhibition of action, prior to IFG (Husain)

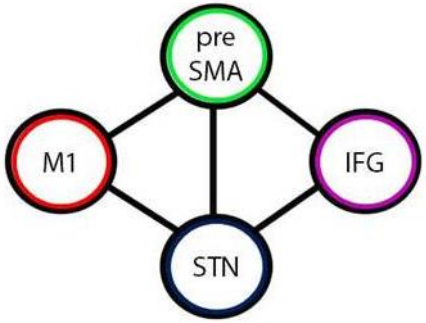




Inferior frontal gyrus (rIFG)
(i) Inhibiting actions (Aron, Poldrack, Neurbert)
(ii) orienting to relevant events (Sharp, Hampshire)

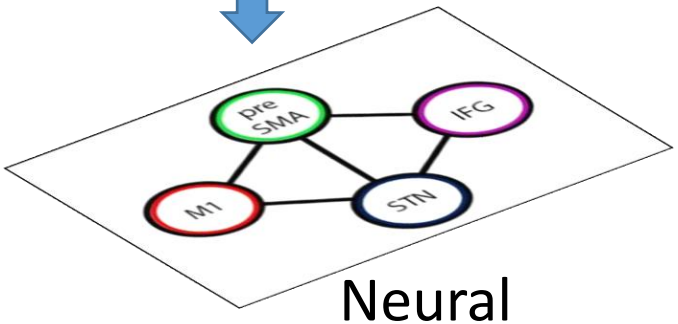
Subthalamic nucleus (STN)
brakes the thalamic outputs of the basal ganglia
(Frank, Strafella, Forstmann)





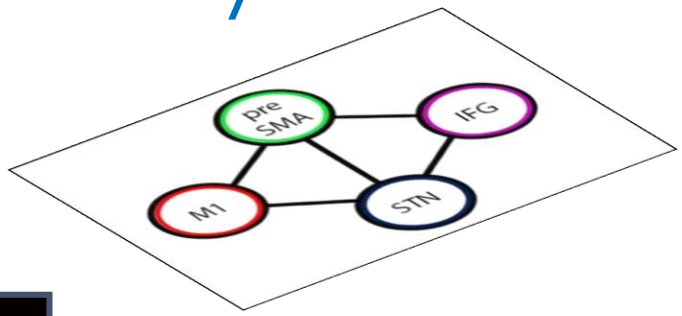
pre
SMA
M1
IFG
STN

Dynamic causal modelling (DCM) to study connectivity of the stopping network

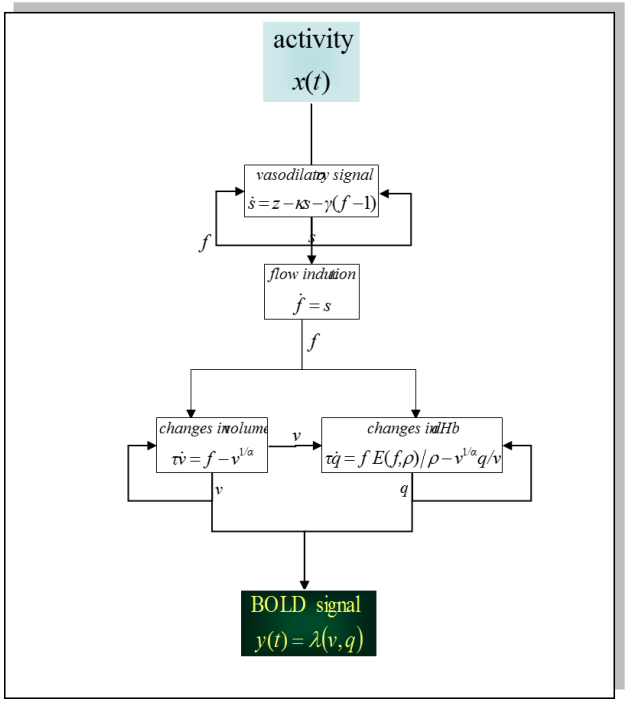


Neural

≠

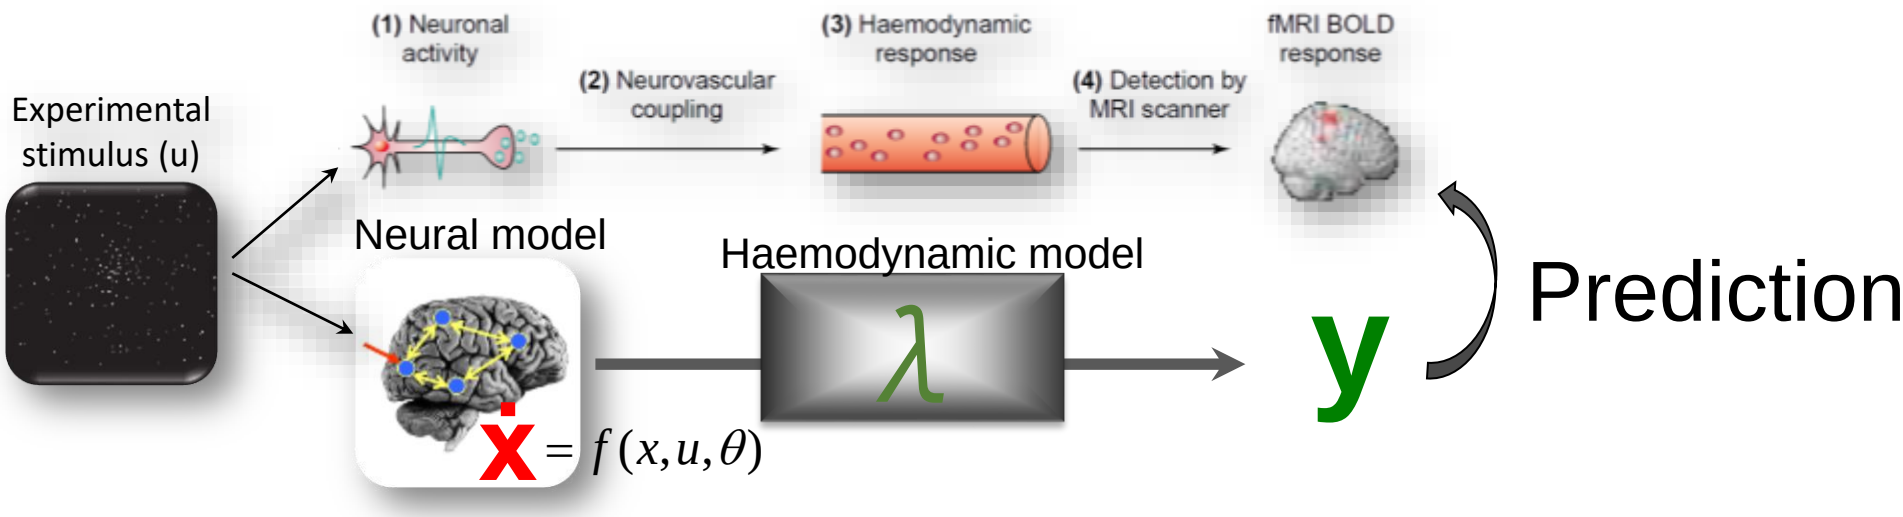


Haemodynamic



The aim of DCM is to estimate <u>parameters at the neuronal and vascular levels</u> such that the modelled and measured BOLD signals are optimally similar (maximising model evidence, F)

DCM for fMRI



- The modelled neuronal dynamics ($\dot{x}$) are transformed into region-specific BOLD signals (**y**) by a hemodynamic model (**λ**)

System is modelled at its neuronal level (not directly accessible to fMRI).

M/EEG

MEG for dementia?

To open the bottleneck in drug development for dementia

To de-risk and accelerate early phase clinical trials

→With a new range of *in vivo* assays,

1. Sensitive to presence of disease
2. Sensitive to progression of disease
3. Elucidate disease mechanisms
4. Trial-ready eg. reliable, scalable

Test disease group: bv-FTD and PSP

Convergent phenotypes (Murley Brain 2020)

personality, impulsivity, apathy, social cognition

akinetic-rigidity, mixed movement disorder

poor survival (3-4 years from diagnosis)

AND convergent neurophysiology

(Sami Brain 2018; Hughes JOCN 2015; Cope J Neurosci 2022)

A brief history of MEG in dementia

- Sensitive and very well tolerated by patients
  (Hughes et al Brain 2011; JoCN 2013, Neuroimage 2013)

A brief history of MEG in FTD/PSP

- Sensitive and very well tolerated by patients
- Convergent physiology, TF and functional connectivity

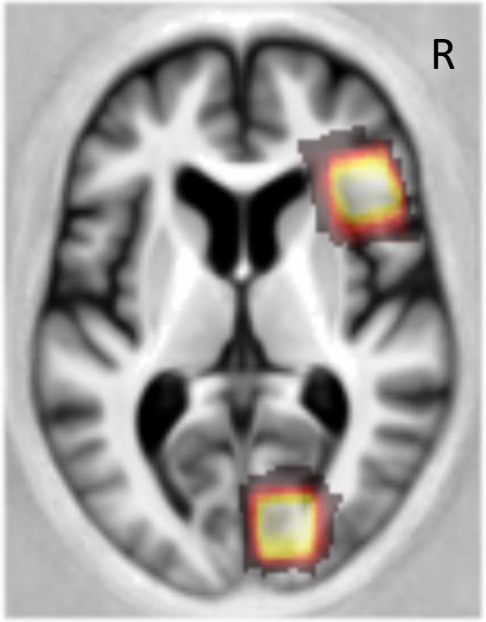
  Sami et al Brain 2018 – Hughes et al Brain 2018

A brief history of MEG in FTD/PSP

- Sensitive and very well tolerated by patients
- Convergent physiology, TF and connectivity
- Validation of GABA-ergic deficits

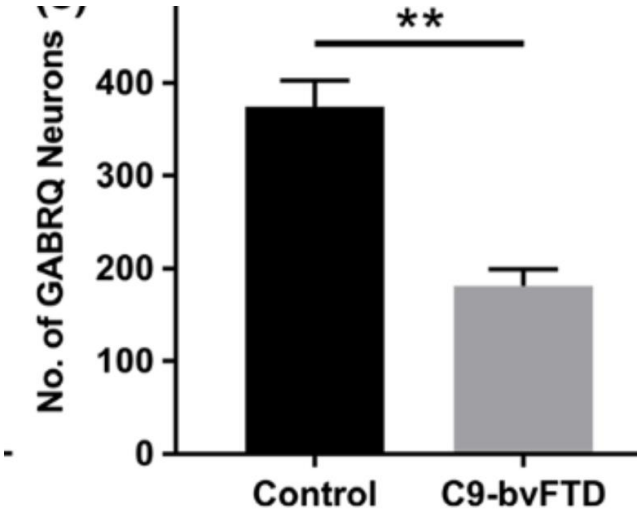
Restoring GABA-ergic function

GABA: the principal inhibitory neurotransmitter reduced by frontotemporal dementia and progressive supranuclear palsy

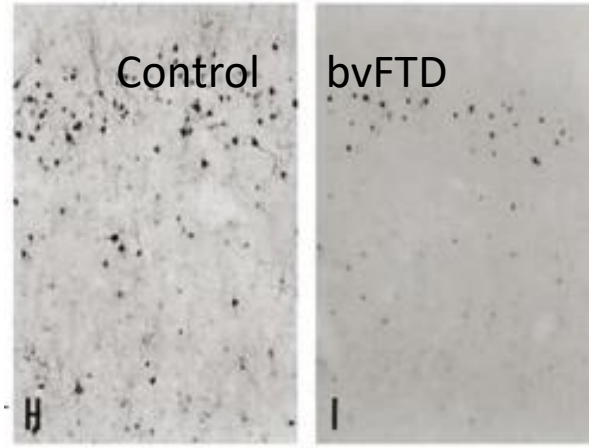


in vivo spectroscopy by 7T

Loss of GABA RQ neurons in PFC



Calbindin



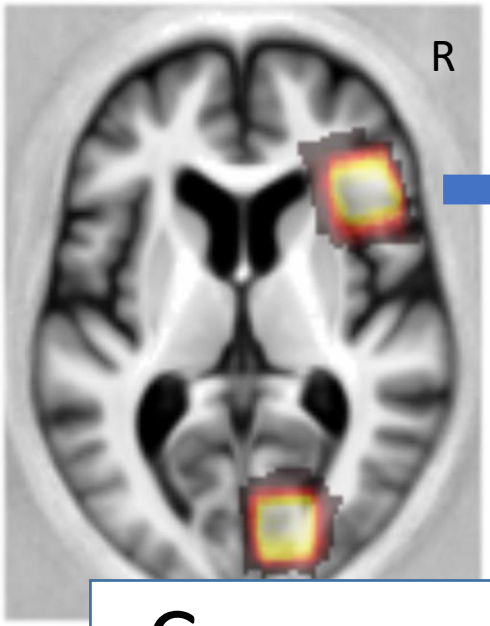
Murley et al, Brain 2020b

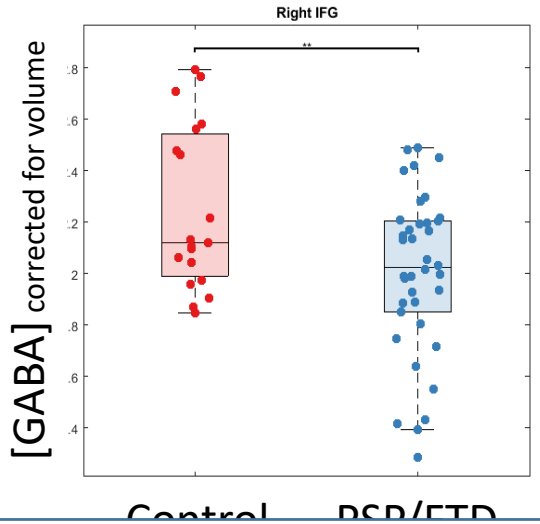
Murley and Rowe, Brain 2018

Gami-Patel et al, Neuropath Appl Neurop 2019

Restoring GABA-ergic function

GABA: in vivo quantification by sLaser MR Spectroscopy at 7T, with LC modelling





People with PSP or FTD type dementias are (***sometimes***) deficient in prefrontal cortical GABA

This **loss of inhibitory neurotransmission correlates with impulsivity**

in viv

Can we restore function by enhancing GABA in Frontotemporal dementia?

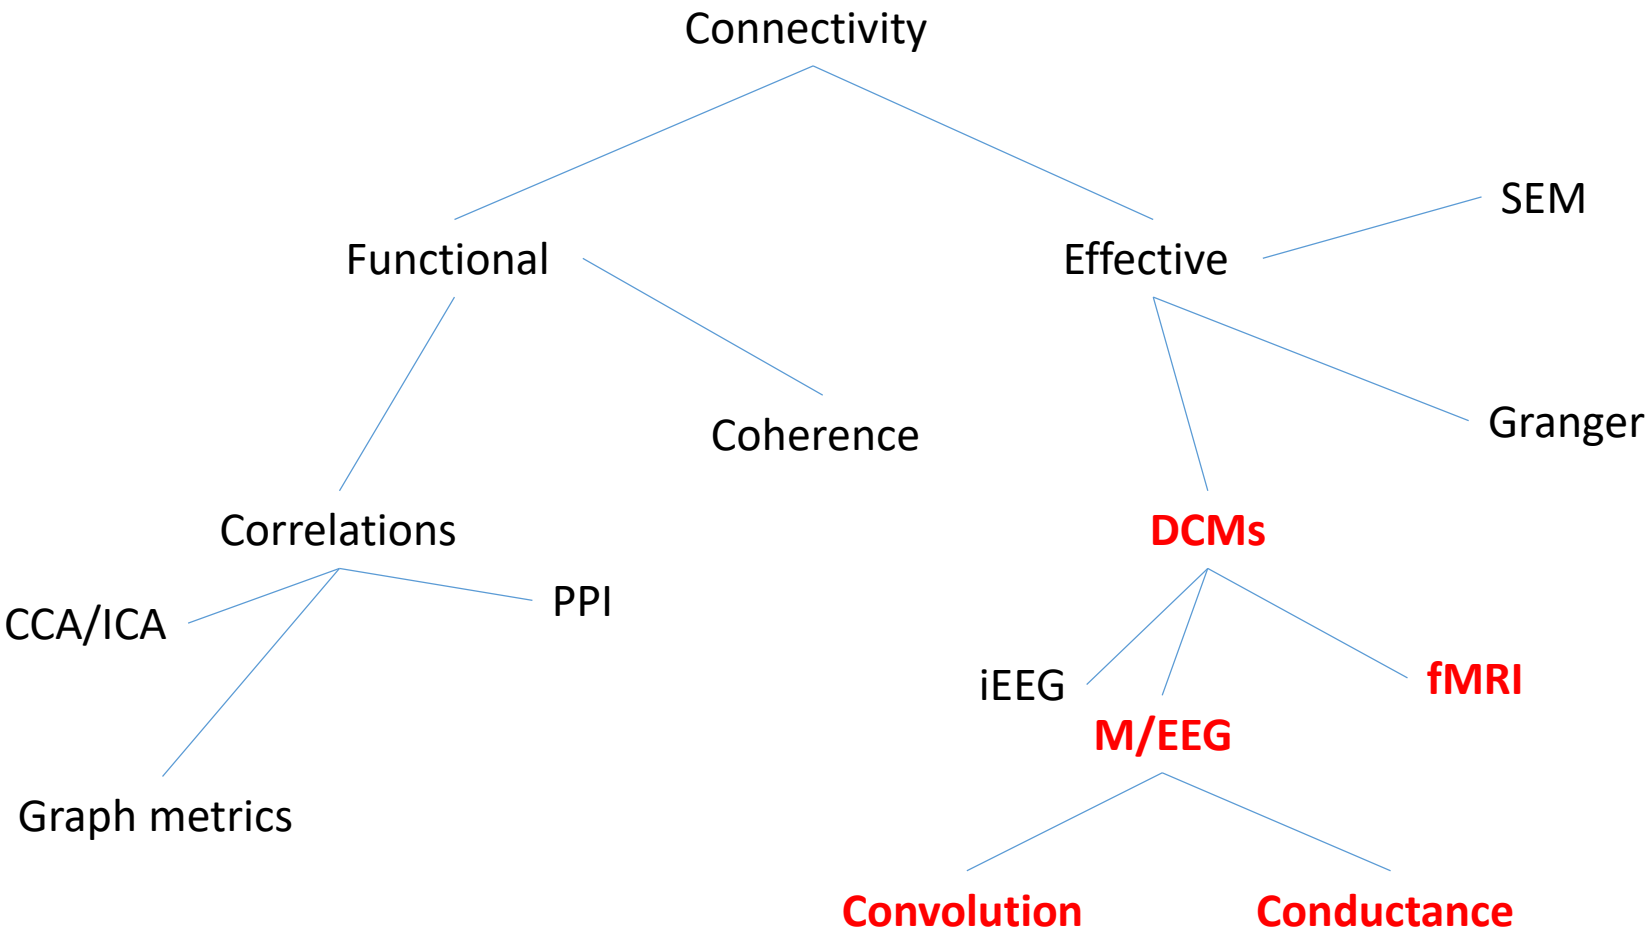
Summary:
DCM in the family of brain connectivity methods



Summary

To de-risk and accelerate early phase clinical trials with new MEG assays ….

1. Sensitive to presence of disease

Summary

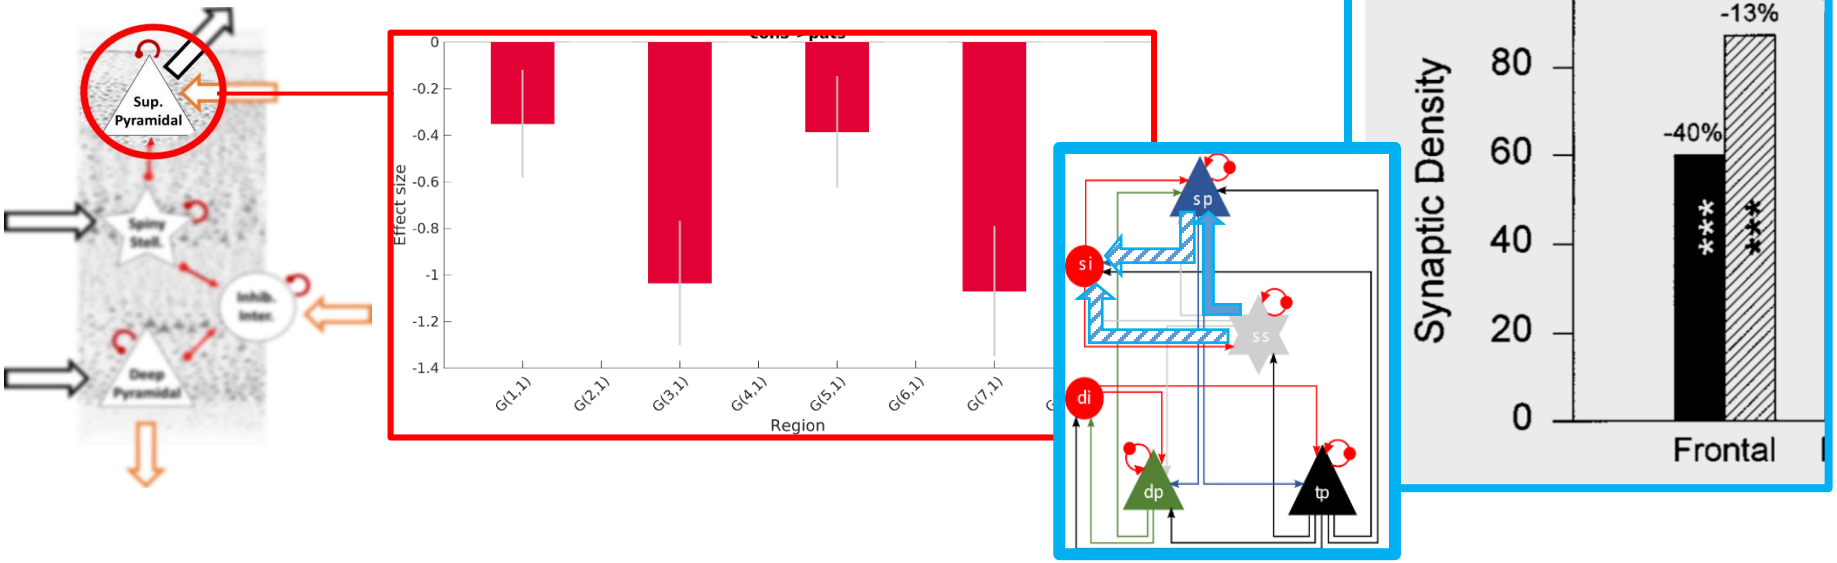
To de-risk and accelerate early phase clinical trials with new MEG assays ….

1. Sensitive to presence of disease (AD, PSP, FTD, PD)
2. Sensitive to progression of disease (AD)

Summary

To de-risk and accelerate early phase clinical trials with new MEG assays ….

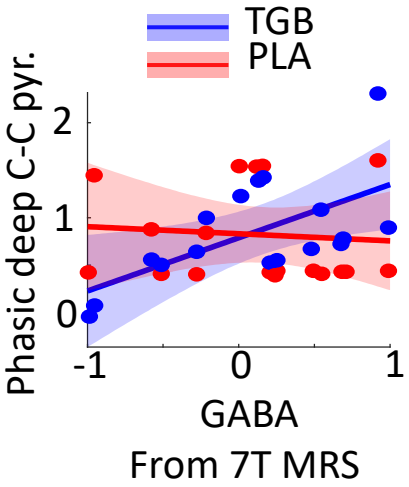
1. Sensitive to presence of disease
2. Sensitive to progression of disease
3. Elucidate disease mechanisms (DCM)

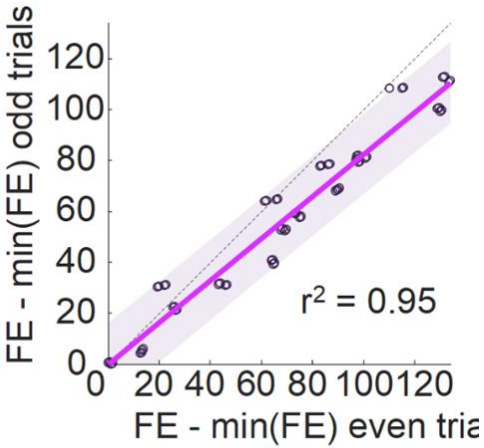


Summary

To de-risk and accelerate early phase clinical trials with new MEG assays ….

1. Sensitive to presence of disease
2. Sensitive to progression of disease
3. Elucidate disease mechanisms
4. Trial-ready eg. ***reliable***, scalable, ***sensitive to drug***





Why choose Dynamic causal modelling ?

1. models interactions at the neuronal (not haemodynamic or sensor/lfp level).

2. can include complex networks, reciprocal connections and loops, biologically plausible systems with feedforward and feedback connectivity….
   THEORETICAL AND ANATOMICAL MOTIVATION

3. can compare models/networks (Bayesian model selection)
   nested and non-nested models, families of models,
   use Free energy estimate of model evidence (adjusted for complexity)
   DESIGN YOUR STUDY AND FRAME HYPOTHESES WITH BMS IN MIND

4. applies to single subjects, heterogenous groups, & interventions

5. is easy to use and simple to understand…

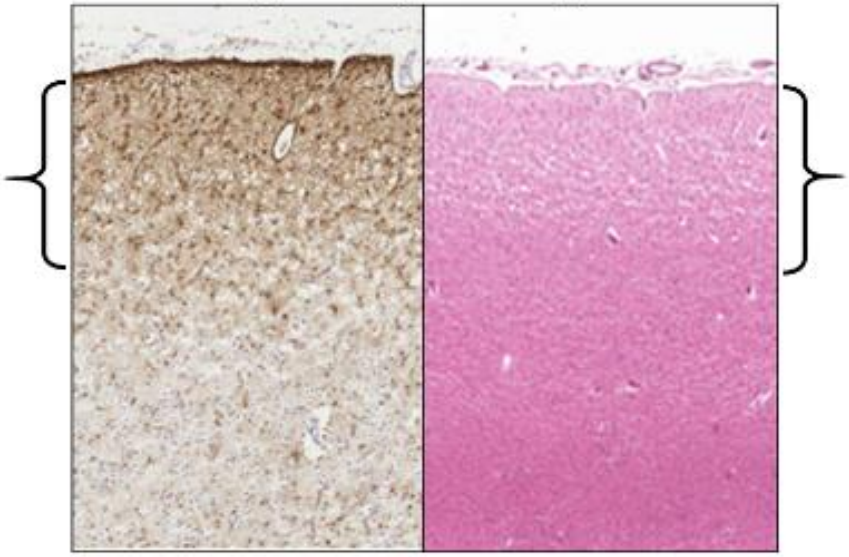
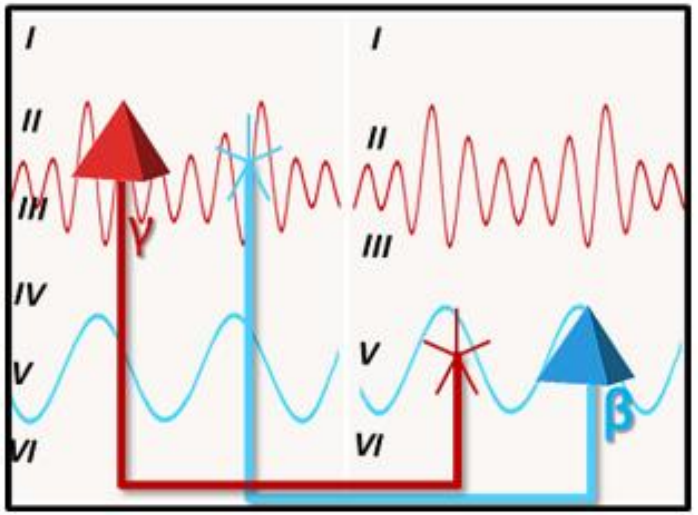
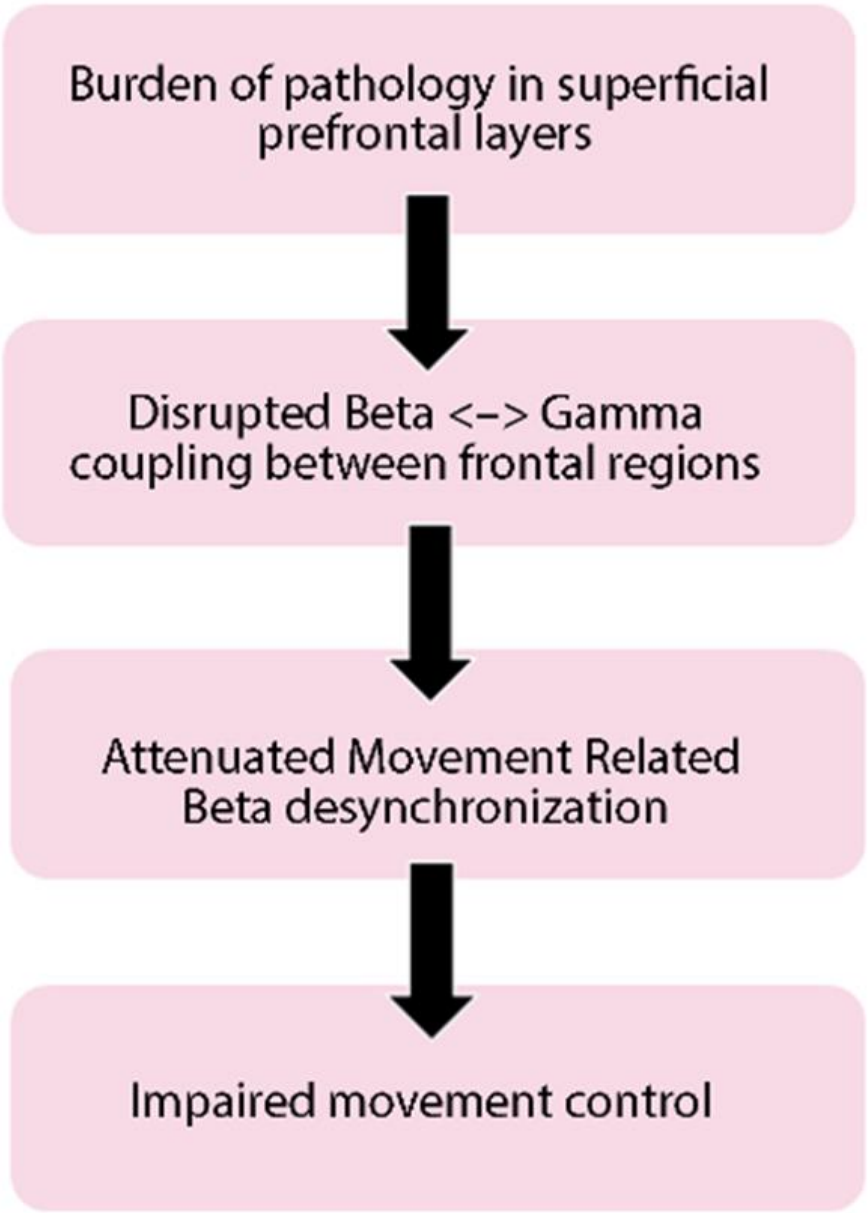
b) Laminar specific pathology in bvFTD

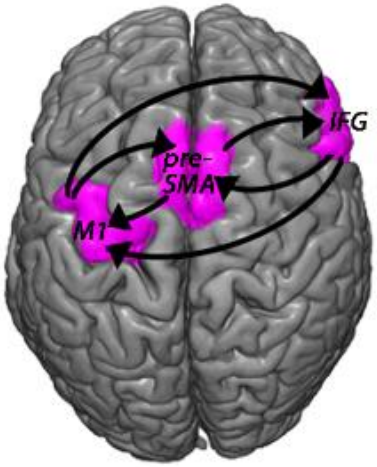


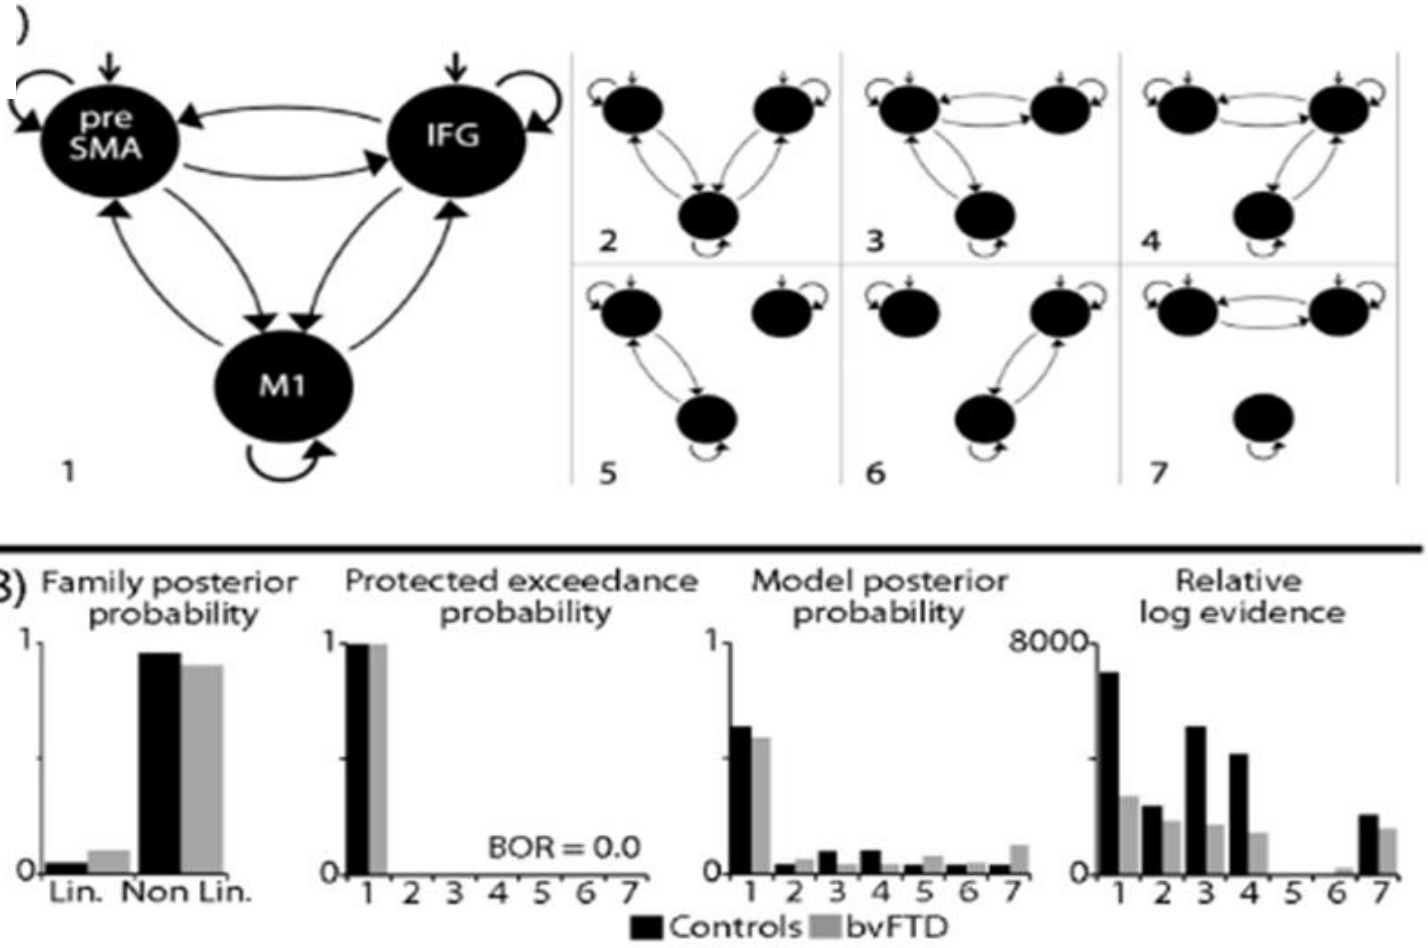
d) Schematic framework for laminar oscillatory connectivity



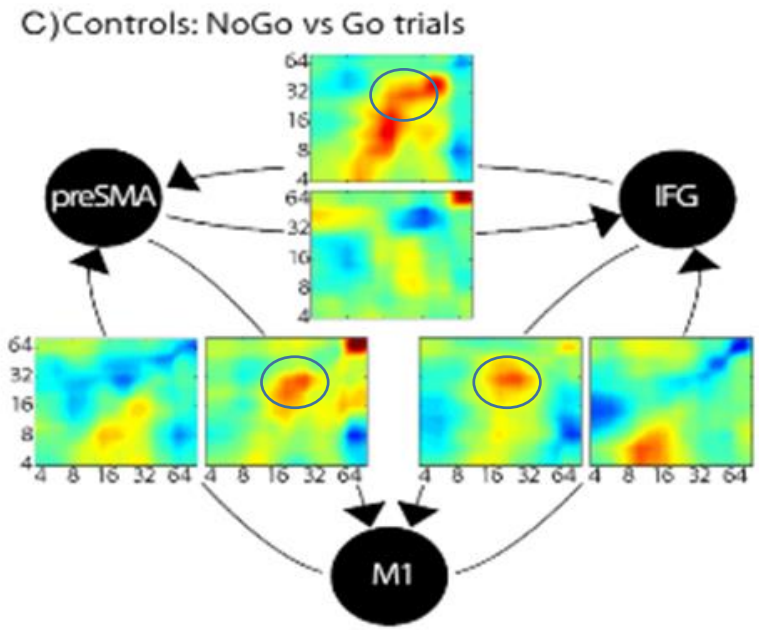
e) Hypothesis

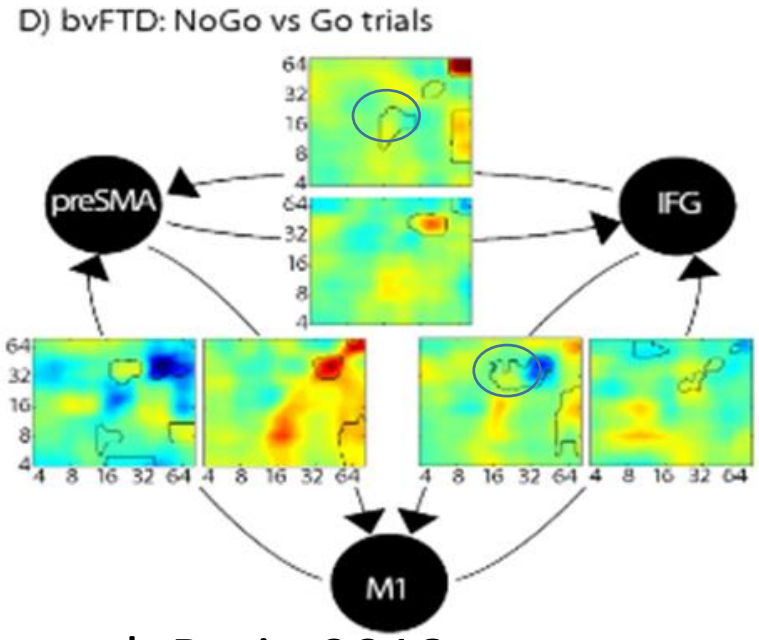






Hughes et al, Brain 2018





All trials - FTD loss of connectivity of the inferior frontal gyrus, particularly for gamma band interactions and theta to alpha coupling. Gamma connectivity between preSMA and motor cortex was enhanced.

NoGo vs Go: In controls, M1 greater beta/gamma coupling from IFG and preSMA, and from IFG to preSMA (top).

In FTD (bottom), a distinct loss of this coupling from IFG to preSMA and M1. Reciprocal frequency couplings are reduced.
FTD Note increase in positive and negative gamma to gamma coupling between preSMA and M1, and

The self-connections (not shown) also reveal a beta desynchronization by theta and alpha to beta couplings, which are diminished in patients.

Hughes et al, Brain 2018
